Table of Contents

- Configure and apply file security on NTFS files and folders using the CLI 1
 - Create an NTFS security descriptor 1
 - Add NTFS DACL access control entries to the NTFS security descriptor 1
 - Create security policies 3
 - Add a task to the security policy 3
 - Apply security policies 5
 - Monitor the security policy job 5
 - Verify the applied file security 6

Configure and apply file security on NTFS files and folders using the CLI

Create an NTFS security descriptor

Creating an NTFS security descriptor (file security policy) is the first step in configuring and applying NTFS access control lists (ACLs) to files and folders residing within storage virtual machines (SVMs). You can associate the security descriptor to the file or folder path in a policy task.

About this task

You can create NTFS security descriptors for files and folders residing within NTFS security-style volumes, or for files and folders residing on mixed security-style volumes.

By default, when a security descriptor is created, four discretionary access control list (DACL) access control entries (ACEs) are added to that security descriptor. The four default ACEs are as follows:

Object	Access type	Access rights	Where to apply the permissions
BUILTIN\Administrators	Allow	Full Control	this-folder, sub-folders, files
BUILTIN\Users	Allow	Full Control	this-folder, sub-folders, files
CREATOR OWNER	Allow	Full Control	this-folder, sub-folders, files
NT AUTHORITY\SYSTEM	Allow	Full Control	this-folder, sub-folders, files

You can customize the security descriptor configuration by using the following optional parameters:

- Owner of the security descriptor
- Primary group of the owner
- Raw control flags

The value for any optional parameter is ignored for Storage-Level Access Guard. See the man pages for more information.

Add NTFS DACL access control entries to the NTFS security descriptor

Adding DACL (discretionary access control list) access control entries (ACEs) to the NTFS security descriptor is the second step in configuring and applying NTFS ACLs to a

file or folder. Each entry identifies which object is allowed or denied access, and defines what the object can or cannot do to the files or folders defined in the ACE.

About this task

You can add one or more ACEs to the security descriptor's DACL.

If the security descriptor contains a DACL that has existing ACEs, the command adds the new ACE to the DACL. If the security descriptor does not contain a DACL, the command creates the DACL and adds the new ACE to it.

You can optionally customize DACL entries by specifying what rights you want to allow or deny for the account specified in the `-account` parameter. There are three mutually exclusive methods for specifying rights:

- Rights
- Advanced rights
- Raw rights (advanced-privilege)

If you do not specify rights for the DACL entry, the default is to set the rights to `Full Control`.

You can optionally customize DACL entries by specifying how to apply inheritance.

The value for any optional parameter is ignored for Storage-Level Access Guard. See the man pages for more information.

Steps

1. Add a DACL entry to a security descriptor: `vserver security file-directory ntfs dacl add -vserver vserver_name -ntfs-sd SD_name -access-type {allow|deny} -account name_or_SID optional_parameters`

```
vserver security file-directory ntfs dacl add -ntfs-sd sd1 -access-type deny
-account domain\joe -rights full-control -apply-to this-folder -vserver vs1
```

2. Verify that the DACL entry is correct: `vserver security file-directory ntfs dacl show -vserver vserver_name -ntfs-sd SD_name -access-type {allow|deny} -account name_or_SID`

```
vserver security file-directory ntfs dacl show -vserver vs1 -ntfs-sd sd1
-access-type deny -account domain\joe
```

```
Vserver: vs1
Security Descriptor Name: sd1
    Allow or Deny: deny
    Account Name or SID: DOMAIN\joe
    Access Rights: full-control
Advanced Access Rights: -
    Apply To: this-folder
    Access Rights: full-control
```

Create security policies

Creating a file security policy for SVMs is the third step in configuring and applying ACLs to a file or folder. A policy acts as a container for various tasks, where each task is a single entry that can be applied to files or folders. You can add tasks to the security policy later.

About this task

The tasks that you add to a security policy contain associations between the NTFS security descriptor and the file or folder paths. Therefore, you should associate the security policy with each SVM (containing NTFS security-style volumes or mixed security-style volumes).

Steps

1. Create a security policy: `vserver security file-directory policy create -vserver vserver_name -policy-name policy_name`

```
vserver security file-directory policy create -policy-name policy1 -vserver vs1
```

2. Verify the security policy: `vserver security file-directory policy show`

```
vserver security file-directory policy show
      Vserver          Policy Name
-----
      vs1              policy1
```

Add a task to the security policy

Creating and adding a policy task to a security policy is the fourth step in configuring and applying ACLs to files or folders in SVMs. When you create the policy task, you associate the task with a security policy. You can add one or more task entries to a security policy.

About this task

The security policy is a container for a task. A task refers to a single operation that can be done by a security policy to files or folders with NTFS or mixed security (or to a volume object if configuring Storage-Level Access Guard).

There are two types of tasks:

- File and directory tasks

Used to specify tasks that apply security descriptors to specified files and folders. ACLs applied through file and directory tasks can be managed with SMB clients or the ONTAP CLI.

- Storage-Level Access Guard tasks

Used to specify tasks that apply Storage-Level Access Guard security descriptors to a specified volume. ACLs applied through Storage-Level Access Guard tasks can be managed only through the ONTAP CLI.

A task contains definitions for the security configuration of a file (or folder) or set of files (or folders). Every task in a policy is uniquely identified by the path. There can be only one task per path within a single policy. A policy cannot have duplicate task entries.

Guidelines for adding a task to a policy:

- There can be a maximum of 10,000 tasks entries per policy.
- A policy can contain one or more tasks.

Even though a policy can contain more than one task, you cannot configure a policy to contain both file-directory and Storage-Level Access Guard tasks. A policy must contain either all Storage-Level Access Guard tasks or all file-directory tasks.

- Storage-Level Access Guard is used to restrict permissions.

It will never give extra access permissions.

When adding tasks to security policies, you must specify the following four required parameters:

- SVM name
- Policy name
- Path
- Security descriptor to associate with the path

You can customize the security descriptor configuration by using the following optional parameters:

- Security type
- Propagation mode
- Index position
- Access control type

The value for any optional parameter is ignored for Storage-Level Access Guard. See the man pages for more information.

Steps

1. Add a task with an associated security descriptor to the security policy: `vserver security file-directory policy task add -vserver vserver_name -policy-name policy_name -path path -ntfs-sd SD_nameoptional_parameters`

`file-directory` is the default value for the `-access-control` parameter. Specifying the access control type when configuring file and directory access tasks is optional.

```
vserver security file-directory policy task add -vserver vs1 -policy-name
policy1 -path /home/dir1 -security-type ntfs -ntfs-mode propagate -ntfs-sd sd2
-index-num 1 -access-control file-directory
```

2. Verify the policy task configuration: `vserver security file-directory policy task show -vserver vserver_name -policy-name policy_name -path path`

```
vserver security file-directory policy task show
```

```
Vserver: vs1
Policy: policy1
```

Index	File/Folder	Access	Security	NTFS	NTFS
Security	Path	Control	Type	Mode	
Descriptor Name					
-----	-----	-----	-----	-----	

1	/home/dir1	file-directory	ntfs	propagate	sd2

Apply security policies

Applying a file security policy to SVMs is the last step in creating and applying NTFS ACLs to files or folders.

About this task

You can apply security settings defined in the security policy to NTFS files and folders residing within FlexVol volumes (NTFS or mixed security style).

Step

1. Apply a security policy: `vserver security file-directory apply -vserver vserver_name -policy-name policy_name`

```
vserver security file-directory apply -vserver vs1 -policy-name policy1
```

The policy apply job is scheduled and the Job ID is returned.

```
[Job 53322]Job is queued: Fsecurity Apply. Use the "Job show 53322 -id 53322" command to view the status of the operation
```

Monitor the security policy job

When applying the security policy to storage virtual machines (SVMs), you can monitor the progress of the task by monitoring the security policy job. This is helpful if you want to ascertain that the application of the security policy succeeded. This is also helpful if you have a long-running job where you are applying bulk security to a large number of files and folders.

About this task

To display detailed information about a security policy job, you should use the `-instance` parameter.

Step

1. Monitor the security policy job: `vserver security file-directory job show -vserver`

```
vserver_name
```

```
vserver security file-directory job show -vserver vs1
```

Job ID	Name	Vserver	Node	State
53322	Fsecurity Apply	vs1	node1	Success
Description: File Directory Security Apply Job				

Verify the applied file security

You can verify the file security settings to confirm that the files or folders on the storage virtual machine (SVM) to which you applied the security policy have the desired settings.

About this task

You must supply the name of the SVM that contains the data and the path to the file and folders on which you want to verify security settings. You can use the optional `-expand-mask` parameter to display detailed information about the security settings.

Step

1. Display file and folder security settings: `vserver security file-directory show -vserver vserver_name -path path [-expand-mask true]`

```
vserver security file-directory show -vserver vs1 -path /data/engineering  
-expand-mask true
```

```
Vserver: vs1  
File Path: /data/engineering
